Binary Message Protocol

The SkyTraq binary message protocol manual provides the detailed descriptions on the SkyTraq binary protocol serving as a communicating interface between SkyTraq GNSS receivers and an external host such as PC, Notebook and mobile personal device. It is a standard protocol used by all SkyTraq devices and provides users a satisfactory control over the GNSS receivers.

The SkyTraq GNSS receiver outputs standard NMEA messages during normal operation. This NMEA messages may be a scheduled output at a specified rate subject to user's requests. The SkyTraq binary message protocol is designed with cares on reliable transmissions of data, ease & efficiency of implement, and payload independence mechanism which ensure users to retrieve data in a most effective & flexible way. The overall binary protocol messages can be categorized as input and output messages. Input messages provide the functionality to users to control the behavior of the GNSS receiver and to retrieve the detailed information of the GNSS status in real-time. Output messages, on the other hand, are information strings that GNSS receiver responses to requests from hosts and can optionally periodically reports the Position, Velocity and Time (PVT) via NMEA or binary messages.

BINARY MESSAGE STRUCTURE

Message Format

The following picture shows the structure of a binary message.

Start of Sequence	Payload Length (PL)	Payload		Checksum (CS)	End of Sequence
		Message ID	Message Body		
0xA0, 0xA1	Two bytes	Message ID: 1 bytes; Payload up to 65535 bytes		One byte	0x0D, 0x0A

The syntax of the message is shown below.

<0xA0,0xA1><PL><Message ID><Message Body><CS><0x0D,0x0A>

Start of Sequence

This field contains two bytes of values 0xA0, 0xA1 which indicate start of Messages.

Payload Length

The payload length (PL) field contains 16 bits of value which indicates the length of payload.

Payload

The payload field consists of 2 sub-fields, Message ID and Message Body. Message ID field defines the message ID.

Sub-Field	Values
Message ID (ID)	0x01~0xFF
Message Body	Data Bytes

Message Body

The Message Body may further consist of 2 sub-fields, Sub-Message ID (Sub-ID) and Sub-Message Body.

Sub-Field	Values

Sub-Message ID(SID)	0x01~0xFF
Sub-Message Body	Data Bytes

Checksum

Checksum (CS) field is transmitted in all messages. The checksum field is the last field in a message before the end of sequence field. The checksum is the 8-bit exclusive OR of only the payload bytes which start from Message ID until the last byte prior to the checksum byte. A reference to the calculation of CS is provided below,

CS = 0, N=PL;
For n = 0 to N
CS = CS ^ <Payload Byte # n>

End of Sequence

This field contains two bytes of values 0x0D, 0x0A which indicate end of Messages.

Data Byte Ordering

All payloads in binary protocol are transferred in big-endian format. The high order byte is transmitted first followed by the low order byte for data size larger than a byte (e.g. UINT32, DPFP).

Data Type Definition

UINT8	8 bit unsigned integer
UINT16	16 bit unsigned integer
UINT32	32 bit unsigned integer
SINT8	8 bit signed integer
SINT16	16 bit signed integer
SINT32	32 bit signed integer
SPFP	32 bit single precision floating point number
DPFP	64 bit double precision floating point number

MESSAGE FLOW

Host can perform actions to GNSS receiver by issuing a request or a set message. The message flow between Host and GNSS receiver is designed under the considerations of certain reliable transmission. SkyTraq binary message protocol requires an ACK response from the GNSS receiver upon receiving a successful input message and on the other hand, requires a NACK response from the receiver to a failed input message. Figure 1 shows a message flow that a host requests information from GNSS receiver and the GNSS receiver responses with an ACK and information respectively. Figure 2 shows a message flow with un-successful input message. Therefore, all requests (input messages) will have a corresponding ACK or NACK to be related with. However, output messages will not require the host to confirm by an ACK or NACK back in current design.

				1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19			

Field	Name	Example(hex)	Description	Type	Unit

2-3	index	0013	Refer to Appendix B for available Datum	UINT16	
4	Ellip idx	07	Refer to Appendix A for available Value	UINT8	
5-6	Delta X	FF7A	Refer to Appendix A and B for available Delta X	SINT16	Meter
7-8	Delta Y	FF97	Refer to Appendix A and B for available Delta Y	SINT16	Meter
9-10	Delta Z	FED9	Refer to Appendix A and B for available Delta Z	SINT16	Meter
11-14	Semi-major axis	007DDF39	Refer to Appendix A	UINT32	
15-18	Inversed Flattening	0046F410	Refer to Appendix A	UINT32	
19	Attributes	00	0: update to SRAM 1: update to both SRAM & FLASH	UINT8	
Payload Length : 19 bytes					

1. In order to reduce number of bytes to send in the configure datum command, the Semi-Major Axis is to be deducted by 6,370,000, with the result multiplied by 1,000.
   Thus if converting 6,378,249.145 the result would be: 6,378,249.145 – 6,370,000 equals 8,249.145 And converting 8,249.145 x 1000 to hex is 007DDF39.
2. Same as for Inversed Flattening which is to be deducted by 293; with the result multiplied by 10,000,000 then converted to hex.
3. The exception is: the Inversed Flattening for Ellipsoid index 20 and 23 will lose precision after deducting by 293, multiply by 10,000,000 and convert to hex. Therefore, upon receiving the configure datum command, our firmware will use the internal hardcoded inversed flattening values for of 20 and 23, regardless of what is sent in the set datum command.

Payload Length : 31 bytes					

*1: supported only in Venus838LPx-T, S1216F8-T timing mode receivers.

Remark:

When using PVT Mode, precision 1PPS won't be generated with less than 4 satellites.
When using Survey Mode, survey length need to be given, the receiver will survey its location for number of specified points, and then change to Static Mode such that precision 1PPS will still be generated with 1 satellite in view.

Use Static Mode when location is known, latitude/longitude/altitude need to be set, and receiver will generate precision 1PPS output down to 1 satellite in view.

For attribute setting specifying "update to SRAM", it will make the setting take effect in the current session. Later if the receiver is turned off and SRAM / RTC backup supply source is still provided, then upon power up receiver will go into survey process if Survey Mode was chosen, or pinned to a fixed location if Static Mode was chosen. If without backup supply source and recycling power, the receiver will start in the default Survey Mode.

For attribute setting specifying "update to both SRAM and Flash", it will make the setting take effect in the current session. Later if the receiver is turned off then upon power up receiver will go into survey process if Survey Mode was chosen, or pinned to a fixed location if Static Mode was chosen.

The time of week is transmitted by GPS satellites, but only the bottom 10 bits of the week number are transmitted. This means valid range is from 0 to 1023, until it reaches 1023 after which it will "roll over" back to zero.
The 1st week rollover occurred in 1999 and the 2nd will be in 2019.

How to decide default week rollover times?

SkyTraq receivers solve this problem by assuming that all week numbers must be at least as large as a reference rollover week number. This reference rollover week number is hard-coded into the firmware at compile time and is normally set a few weeks before the software is completed, but it can be adjusted by command "*Configure UTC Reference Time Sync to GPS Time*".

For example :

User just input reasonable UTC time they want, SkyTraq receivers will transform this reference time to proper week rollover times automatically.

It is important to set the reference rollover week number appropriately when supplying SkyTraq receivers with simulated signals, especially when the scenarios are in the past.
